

Time Series Analysis using Facebook Prophet

Last Updated : 21 Nov, 2024

Time series analysis is one of the important methodologies that helps us to understand the hidden patterns in a dataset that is too related to the time at which it is being recorded. The article aims to explore the fundamentals of time series analysis and demonstrates the **analysis using Facebook Prophet**.

What is Time Series Analysis?

Time series analysis is a statistical approach that entails gathering data at consistent intervals to recognize patterns and trends. This methodology is employed for making well-informed decisions and precise forecasts by leveraging insights derived from historical data.

And the process of predicting the future values of the data by analyzing the previous trends and patterns hidden in the data is known as time series forecasting. Time series forecasting can be done using various forecasting techniques like [ARIMA](#), [SARIMA](#), Prophet, Theta and other statistical method. Time series data is a sequential data hence, [deep learning](#)-based methods like [RNN](#), [LSTM](#), [BLSTM](#) and [GRU](#) are also used for time series forecasting.

Key components of Time Series analysis

Grasping these dependencies is essential for accurate predictions and gaining valuable insights.

2. Trend analysis involves recognizing the fundamental direction or long-term movement in a time series, whether it is upward, downward, or stable. This understanding provides insights into the overall trajectory of the data.
3. Seasonal patterns, observed in numerous time series, depict recurring cycles at fixed intervals, such as daily, monthly, quarterly, or yearly. Analyzing these patterns through seasonal analysis helps identify and comprehend their periodic nature.
4. Time series data often incorporates random fluctuations or noise that lacks a specific trend or pattern. It is crucial to eliminate this noise to unveil meaningful information within the data.

Facebook Prophet Library

Prophet is an open-source tool from Facebook used for forecasting time series data which helps businesses understand and possibly predict the market. It is based on a decomposable additive model where non-linear trends fit with seasonality, it also takes into account the effects of holidays. Before we head right into coding, let's learn certain terms that are required to understand this.

- **Trend:** The trend shows the tendency of the data to increase or decrease over a long period of time and it filters out the seasonal variations.
- **Seasonality:** Seasonality is the variations that occur over a short period of time and is not prominent enough to be called a "trend".

Understanding the Prophet Model

The general idea of the model is similar to a [generalized additive model](#). The "Prophet Equation" fits, as mentioned above, trends, seasonality, and holidays. This is given by,

$$y(t) = g(t) + s(t) + h(t) + e(t)$$

- $h(t)$ refers to effects of holidays to the forecast
- $e(t)$ refers to the unconditional changes that is specific to a business or a person or a circumstance. It is also called the error term.
- $y(t)$ is the forecast.

Need of Facebook Prophet

We need it because, although the basic decomposable additive model looks simply, the calculation of the terms within is hugely mathematical. If you do not know what you are doing, it may lead to making wrong forecasts, which might have severe repercussions in the real world. So, to automate this process, we are going to use Prophet. However, to understand the math behind this process and how Prophet actually works, let's see how it forecasts the data.

Prophet provides us with two models (however, newer models can be written or extended according to specific requirements).

1. Logistic Growth Model
2. Piece-Wise Linear Model

By default, Prophet uses a piece-wise linear model, but it can be changed by specifying the model. Choosing a model is delicate as it is dependent on a variety of factors such as company size, growth rate, business model, etc., If the data to be forecasted, has saturating and non-linear data (grows non-linearly and after reaching the saturation point, shows little to no growth or shrink and only exhibits some seasonal changes), then logistic growth model is the best option. Nevertheless, if the data shows linear properties and had growth or shrink trends in the past then, the piece-wise linear model is a better choice. The logistic growth model is fit using the following statistical equation,

$$g(t) = \frac{C}{1 + e^{-k(t-m)}}$$

where,

The piece-wise linear model is fit using the following statistical equations,

$$y = \begin{cases} \beta_0 + \beta_1 x, & \text{if } x \leq c, \\ \beta_0 - \beta_2 c + (\beta_1 + \beta_2)x, & \text{if } x > c. \end{cases}$$

where c is the trend change point (it defines the change in the trend). β_2 is the trend parameter and can be tuned as per requirement for forecasting.

Implementation – Analyzing Time Series Data using Prophet

Now let's try and build a model that is going to forecast the number of passengers for the next five years using time series analysis.

Installing Prophet and Other Dependencies

Install pandas for data manipulation and for the dataframe data structure.

```
!pip install pandas
```

Install Prophet for time series analysis and forecasting.

```
!pip install prophet
```

Importing Required Libraries

```
import pandas as pd
from prophet import Prophet
from prophet.plot import add_changepts_to_plot
```

Loading Air Passenger Dataset

Now let's load the csv file in the [pandas](#) data frame. The dataset contains the number of air passengers in the USA from January 1949 to December 1960.

```
"/master/airpassengers.csv")
data = pd.read_csv(url)
data.head()
```

Output:

	Month	#Passengers
0	1949-01	112
1	1949-02	118
2	1949-03	132
3	1949-04	129
4	1949-05	121

Facebook Prophet predicts data only when it is in a certain format. The dataframe with the data should have a column saved as *ds* for time series data and *y* for the data to be forecasted. Here, the time series is the column *Month* and the data to be forecasted is the column *#Passengers*. So, let's make a new DataFrame with new column names and the same data. Also, *ds* should be in a DateTime format.

```
df = pd.DataFrame()
df['ds'] = pd.to_datetime(data['Month'])
df['y'] = data['#Passengers']
df.head()
```

Output:

	ds	y
0	1949-01-01	112
1	1949-02-01	118
2	1949-03-01	132
3	1949-04-01	129
4	1949-05-01	121

Initializing a Prophet Model

```
m = Prophet()
m.fit(df)
```

We want our model to predict the next 5 years, that is, till 1965. The frequency of our data is 1 month and thus for 5 years, it is $12 * 5 = 60$ months. So, we need to add 60 to more rows of monthly data to a dataframe.

```
future = m.make_future_dataframe(periods=12 * 5,
                                freq='M')
```

Now in the *future* dataframe we have just *ds* values, and we should predict the *y* values.

```
forecast = m.predict(future)
forecast[['ds', 'yhat', 'yhat_lower',
          'yhat_upper', 'trend',
          'trend_lower', 'trend_upper']].tail()
```

Output:

	ds	yhat	yhat_lower	yhat_upper	trend
trend_lower \					
199	1965-07-31	723.847886	695.131427	753.432671	656.874802
					649.871409
200	1965-08-31	677.972773	649.074148	707.203918	660.006451
					652.869703
201	1965-09-30	640.723643	612.025440	670.377970	663.037079
					655.722042
202	1965-10-31	610.965273	580.772823	641.770085	666.168728
					658.710202
203	1965-11-30	640.594175	611.016447	669.582208	669.199356
					661.513728
trend_upper					
199		663.255178			

Plotting the Forecast Data

Table *ds*, as we know, is the time series data. *yhat* is the prediction, *yhat_lower*, and *yhat_upper* are the uncertainty levels (it basically means the prediction and actual values can vary within the bounds of the uncertainty levels). Next up we have a *trend* that shows the long-term growth, shrink, or stagnancy of the data, *trend_lower*, and *trend_upper* is the uncertainty levels.

```
fig1 = m.plot(forecast, include_legend=True)
```

Output:

The below image shows the basic prediction. The light blue is the uncertainty level (*yhat_upper* and *yhat_lower*), the dark blue is the prediction (*yhat*) and the black dots are the original data. We can see that the predicted data is very close to the actual data. In the last five years, there is no “actual” data, but looking at the performance of our model in years where data is available it is

Output:

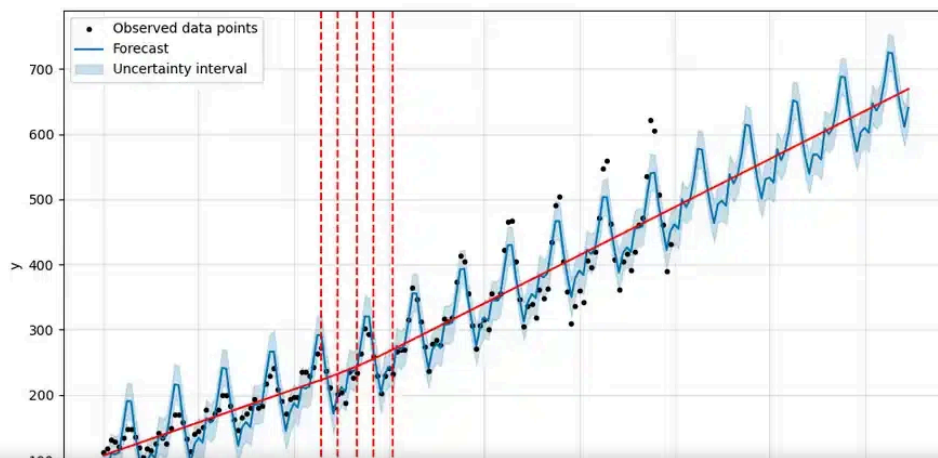

Trends and Seasonality in Time Series Data

The below images show the trends and seasonality (in a year) of the time series data. We can see there is an increasing trend, meaning the number of air passengers has increased over time. If we look at the seasonality graph, we can see that June and July is the time with the most passengers in a given year.

```
fig = m.plot(forecast)
a = add_changepoints_to_plot(fig.gca(),
                             m, forecast)
```

Output:

Add changepoints to indicate the time in rapid trend growths. The dotted red lines show the time when there was a rapid change in the trend of the passengers. Thus, we have seen how we can design a prediction model using Facebook Prophet with only a few lines of code which would have been very difficult to implement using traditional [machine learning](#) algorithms and mathematical and statistical concepts alone.
